THE DAILY, MONTHLY, AND ANNUAL
NORMALS OF PRECIPITATION IN THE
UNITED STATES BASED ON THE
50-YEAR PERIOD, 1873 TO 1922
INCLUSIVE

BY P. C. DAY

Submitted for publication May 14, 1923

Printed by the
Government Printing Office
Washington, D. C.

In order to facilitate theoretical studies of the annual march and distribution of precipitation at the various stations, there have been compiled the consecutive 14-day sums of the actual, unsmoothed precipitation from the beginning of January to the last fortnight of the year, which naturally embrace 15 days. It is believed these data are decidedly superior to the ordinary amounts of precipitation for the usual calendar months which, moreover, are deemed to be too long a period of time in which to bring out certain important characteristics in the progression of these normals has been given the title:

**THE DAILY, MONTHLY, AND ANNUAL NORMALS OF PRECIPITATION
FOR THE UNITED STATES, BASED ON THE 50-YEAR PERIOD,
1878 TO 1927, INCLUSIVE. ALSO SUMS OF THE DAILY VALUES
BY 14-DAY PERIODS THROUGHOUT THE ENTIRE YEAR**

The last general revision of the precipitation normals for the regular first-order stations of the bureau was made in 1907 and embraced data up to 1906, inclusive, so that more than 20 years have elapsed since that time.

Many new first-order stations have been established in that period for which normals are desired, and the addition of more than 20 years to the record already established affords desirable data for recomputing with better results the normals for the older stations of the bureau.

In this revision it seemed desirable to have the normals based uniformly upon a half century of record, and the period, January, 1878, to December, 1927, inclusive, was adopted; all stations having fewer years of record have been corrected to that period, either by interpolating the monthly amounts for the missing years directly from charts of monthly totals of precipitation for the missing years or by correcting the shorter periods to the full 50 years by the usual methods of comparison with the data from near-by stations.

Over the greater part of the country it was possible to safely interpolate the missing monthly amounts by scaling the values from charts of monthly precipitation based on reports from all stations in the immediate vicinity in operation during the respective months and years. On account of the large number of cooperative precipitation observations being made over most sections of the country, their values afforded ready means for interpolation where the topography favored a rather uniform distribution of precipitation over near-by areas. The broken topography with mountains and valleys over much of the western part of the country prohibited direct interpolation in that section from such charts, and here it was necessary to interpolate the missing records by establishing the normal ratios the short-record stations have to near-by long-record stations and applying the ratios to determine the probable data for the missing period of the short-record station using, where feasible, the records of a station on each side of the short-period station and combining the two sets of values.

As a result of these interpolations, a 50-year precipitation normal has been established for each first-order Weather Bureau station in operation at the end of 1927, thereby furnishing comparable data for a half century over all parts of the country.

In establishing the daily normals, all daily precipitation records for each station from 1878 to 1927 were tabulated and the averages determined for each day of the year for that period. Where the periods of observation were less than the 50 years selected, the monthly averages were first corrected to the full 50 years and the average daily values for the actual period of observations were corrected to make their monthly sums exactly equal the new 50-year monthly averages.

As a rule these monthly corrections were comparatively small, and they were distributed through the days of the month arbitrarily, but with a view to harmonizing extreme daily amounts, additive corrections were applied to the smaller daily values, while subtractive corrections were applied to the larger daily amounts.

These average daily values may be at times unduly distorted by occasional heavy rains on a particular date or dates, the effects of which would be naturally overcome only after the lapse of many additional years of record. To overcome the effect of these abnormalities on the corresponding daily values all the latter were smoothed for each station by the usual process of making successive 5-day means and using these values for the daily means throughout the year; thus the mean of the 5-day period, December 30 to January 3, would be used as the normal value for January 1; the mean of December 31 to January 4 would form the mean for January 2, and so on throughout the year, care being taken to see that the final sum of these smoothed daily values exactly equaled the 50-year monthly and annual means.

These normals were put in operation at the greater part of the first-order stations beginning January 1, 1928, but the results of some of the shorter-record stations were not prepared in time for such action, and these began with January 1, 1929.

The total number of these stations is 197. Those having a complete record for the entire period of 50 years is 96; those having from 40 to 49 years of complete record is 54; those 30 to 39 years of complete record is 25; those with 20 to 29 years of complete record is 14; and those with less than 20 years of complete record is 8.

In order to facilitate theoretical studies of the annual march and distribution of precipitation at the various stations, there have been compiled the consecutive 14-day sums of the actual, unsmoothed precipitation, from the beginning of January to the last fortnight of the year, which naturally embraces 15 days. It is believed these data are decidedly superior to the ordinary amounts of precipitation for the unequal calendar months which, moreover, are deemed to be too long a period of time in which to bring out certain important characteristics.

Much assistance in the preparation of these normals has been given the officials in charge of the Weather Bureau stations at Ludington, Mich., and Portland, Me., and by Miss Grace W. Carter and Miss Mary O. Souder of the Climatological Division.

FOR THE YEARS 1878 TO 1927, INCLUSIVE, ALSO SUMS OF THE DAILY VALUES
BY 14-DAY PERIODS THROUGHOUT THE ENTIRE YEAR

The last general revision of the precipitation normals for the regular first-order stations of the bureau was made in 1907 and embraced data up to 1906, inclusive, so that more than 20 years have elapsed since that time.

Many new first-order stations have been established in that period for which normals are desired, and the addition of more than 20 years to the record already established affords desirable data for recomputing with better results the normals for the older stations of the bureau.

In this revision it seemed desirable to have the normals based uniformly upon a half century of record, and the period, January, 1878, to December, 1927, inclusive, was adopted; all stations having fewer years of record have been corrected to that period, either by interpolating the monthly amounts for the missing years directly from charts of monthly totals of precipitation for the missing years or by computing the shorter periods to the full 50 years by the usual methods of comparison with the data from near-by stations.

Over the greater part of the country it was possible to safely interpolate the missing monthly amounts by scaling the values from charts of monthly precipitation based on reports from all stations in the immediate vicinity in operation during the respective months and years. (In stations of the large number of consecutive precipitation observations being made over most sections of the country, their values already means for interpolation when the topography favored a rather uniform distribution of precipitation over near-by areas. The bureau superintended interpolation in that section from such charts, and here it was necessary to interpolate the missing records by establishing the normal ratios the short-record stations have to nearby long-record stations and applying the ratios to determine the probable data for the missing period of the short-record station using, when feasible, the records of a station on each side of the short-period station and combining the two sets of values.)

As a result of these interpolations, a 50-year precipitation normal has been established for each first-order Weather Bureau station in operation at the end of 1927, thereby furnishing comparable data for a half century over all parts of the country. In establishing the daily normals, all daily precipitation records for each station from 1878 to 1927 were tabulated and the averages determined for each day of the year for that period. Where the periods of observation were less than the 50 years selected, the monthly averages were first corrected to the full 50 years and the average daily values for the actual period of observations were corrected to make their monthly sums exactly equal the new 50-year monthly averages.

As a rule these monthly averages were comparatively small, and they were distributed through the days of the month extremely evenly, but with a view to harmonizing extremely heavy, excessive additive corrections were applied to the smaller daily values, while subtractive corrections were applied to the larger daily amounts.

These average daily values may be at times slightly distorted by occasional heavy rains or particular date or dates, the effect of which would be naturally overcome only after the lapse of many additional years of record. To overcome the effect of these abnormalities on the year's corresponding daily values all the latter were smoothed for each station by the usual process of making successive 5-day means and using these values for the daily means throughout the year. Thus the mean of the 5-day period, December 30 to January 3, would be used as the normal value for January 1; the mean of December 21 to January 4 would form the mean for January 2, and so on throughout the year, care being taken to see that the final sum of these smoothed daily values exactly equalled the 50-year monthly and annual means.

These normals were put in operation at the greater part of the first-order stations beginning January 1, 1928, but the results of some of the shorter-record stations were not prepared in time for such action, and these began with January 1, 1929.

The total number of these stations is 197. Those having a complete record for the entire period of 50 years is 95; those having from 40 to 49 years of complete record is 54; those 30 to 39 years of complete record is 28; those with 20 to 29 years of complete record is 14; and those with less than 20 years of complete record is 8.
